

MAUD initiation at K = 18 VISNs: pooled, federated, and meta-analytic GEE

Note.

1. Marginal logistic GEE of in-hospital MAUD initiation across 29,041 hospitalizations of 18,900 unique veterans in 18 VISNs (the unit of federation). Pooled GEE and Fed-GEE give identical odds ratios; Fed-GEE differs only in its interval.

2. Pooled GEE: VISN-clustered sandwich with a normal reference distribution. Fed-GEE: Kauermann-Carroll score-space correction with a t-distribution reference on Bell-McCaffrey degrees of freedom, computed from the VISN summaries alone. Meta-analytic GEE: each VISN fits its own GEE and the estimates are inverse-variance pooled.
